Conductive polymers or, more precisely, intrinsically conducting polymers (ICPs) are organic polymers that conduct electricity. Such compounds may have metallic conductivity or can be semiconductors.The biggest advantage of conductive polymers is their processability, mainly by dispersion.Conductive polymers are generally not thermoplastics, i.e., they are not thermoformable.

Balasubramanian Viswanathan, in Energy Sources, 2017. Faradaic Supercapacitors. FS or pseudocapacitors are different from electrostatic or EDLS capacitors. When a potential is applied to an FS, fast and reversible Faradaic reactions (redox reactions) take place on the electrode materials and involve the passage of charge across the double layer, similar to the charging and discharging ...

Volume Resistivity of polymers material measures how strongly a plastic material opposes the flow of electric current through a volume of cubic specimen. The lower the resistivity the higher the conductivity (electric charges meet a weak resistance to circulation).

Buckingham π theorem (also known as Pi theorem) is used to determine the number of dimensional groups required to describe a phenomena. According to this theorem “the number of dimensionless groups to define a problem equals the total number of variables, n , (like density, viscosity, etc.) minus the fundamental dimensions, p , (like length, time, etc).”
